

AVALANCHE BUILDERS GRANT • 2026

Hypa

Prediction markets, settled on-chain.

BUILT ON AVALANCHE C-CHAIN

LIVE ON FUJI • CONTRACTS VERIFIED

THE PROBLEM

Prediction markets are priced out of their own use case.

Gas exceeds the trade

A user placing a \$2 position cannot pay \$8 in gas to do it. On most L1s the fee is larger than the bet, which structurally excludes the casual trader the category depends on.

Settlement is off-chain

Most platforms hold funds in a custodial ledger and post only summaries on-chain. Users are asked to trust an operator's accounting rather than verify it.

Slow finality breaks the UX

Markets move on live events. If a trade takes 30 seconds to confirm, the interface either lies optimistically or makes the user wait through the moment they were trading on.

THE SOLUTION

Hypa

A binary prediction market where every position, every price change, and every payout is a transaction on Avalanche C-Chain. No custodian, no off-chain ledger, no trust assumption on the operator's books.

1

CONTRACT PER MARKET

Each question is its own deployed contract holding both pools.

2%

PROTOCOL FEE

Taken on winnings at claim time. No fee on losing positions.

~1s

TO FINALITY

Odds visibly move within a second of a trade landing.

0

OFF-CHAIN BALANCES

Contract custody only. Anyone can audit the pools directly.

THE PRODUCT

Shipped and live on Fuji.

Fifteen markets across crypto, sports, politics and tech.
Odds move with real money; history is reconstructed from on-chain events.

TOTAL GAS – 15 MARKET CONTRACTS DEPLOYED

This is a measured figure from our own deployment, not an estimate. Fifteen separate contract deployments cost a rounding error. The same operation on Ethereum mainnet runs into the hundreds of dollars, and every individual bet would carry gas comparable to the bet itself.

→ Sub-second finality

Markets trade on live events. Avalanche consensus lets the interface show a confirmed price change almost immediately, rather than guessing optimistically.

→ EVM compatibility

Standard Solidity and OpenZeppelin primitives. No new VM to learn, which let a small team reach a working, verified product quickly.

→ A subnet path

A production Hypa could run on a dedicated subnet with a custom gas token, letting the protocol subsidise or eliminate gas for traders entirely. That option does not exist on a general-purpose L1.

Factory pattern, indexed reads.

Contracts

A factory deploys one PredictionMarket per question. Each market holds both pools, records positions per address, and handles resolution and claims independently. ReentrancyGuard on all value transfers, checks-effects-interactions ordering, one-time claim flags.

Payout

userShare	stake / winPool
gross	stake + share × losePool
net	gross × 0.98

Reads are free

Browsing markets, viewing odds, and inspecting charts require no wallet. Only trading, resolving, and claiming need a signature.

Two choices worth defending.

DECISION 01

Market creation is admin-gated on-chain

Our first version let anyone create a market. That is more decentralised on paper and worse in practice: a user could create a market, take the other side of every bet, and resolve it in their own favour. Without an oracle, permissionless creation is an attack surface, not a feature.

Polymarket curates every market through an internal team. Kalshi, as a regulated exchange, requires approval per contract. Hypa follows the same pattern for the same reason.

ENFORCED IN SOLIDITY – createMarket reverts for any caller other than the factory admin, and the interface hides the flow entirely unless the connected wallet matches the on-chain admin.

DECISION 02

Chart history is indexed server-side

Contracts store current pool totals, not history. To draw an odds curve we replay BetPlaced events and compute running odds after each trade — real data, no interpolation.

The naive version had every market card query the chain directly. With Avalanche's 2,048-block cap on eth_getLogs, that produced several hundred RPC calls per page load and exhausted rate limits on every provider we tried, including a dedicated endpoint.

THE FIX – a single API route scans all markets once, computes each series, and caches the result. The browser makes one request instead of hundreds, and the RPC credential stays server-side rather than shipping in the client bundle.

ON-CHAIN SETTLEMENT

Complete and working

Full trade lifecycle `bet → resolve → claim`

Admin-gated creation `enforced on-chain`

Server-side event indexer `cached, one scan`

Wallet support `desktop + mobile`

Contract test suite `payout math verified`

Hypa

Verified on Snowtrace

MarketFactory `0x023B2A09...8Cf23`

PredictionMarket `0x6B6F9736...510b9`

Network `Fuji · 43113`

Source `readable on-chain`

Reviewers can read the deployed Solidity directly — the admin gate, the payout math, and the reentrancy guards are all publicly auditable.

What this is not, yet.

We would rather name the gaps than have a reviewer find them. These are the real limits of a v1, and each one maps to a line on the roadmap.

Resolution is centralised

The market owner declares the outcome. There is no oracle, no dispute window, and no economic penalty for resolving dishonestly. This is the single largest gap between Hypa and a fully trustless market, and it is the first item we intend to close.

Binary outcomes only

Each market has exactly two sides. Multi-outcome questions — eight candidates, one winner — need a different contract design with a shared pool.

Pool pricing, not an order book

Odds are the ratio of pool sizes. There is no limit-order matching, and large positions move the price against the trader placing them.

Testnet, unaudited

Deployed to Fuji. No third-party audit has been performed. These contracts should not custody real value in their current state — which is precisely what part of this grant is for.

No liquidity incentives

Nothing currently rewards early participants for making thin markets tradable.

From working to trustless.

PHASE	MILESTONE	OUTCOME
01	Optimistic oracle resolution Proposer stakes a bond on an outcome; a challenge window opens; disputes escalate to a decentralised vote.	Removes the operator from settlement
02	Permissionless creation with a bond Once resolution no longer depends on creator honesty, the admin gate is replaced by a slashable creation stake.	Opens the long tail of markets
03	Multi-outcome markets N outcomes over a shared pool, rather than one binary market per candidate.	Elections, tournaments, races
04	Order book or LMSR pricing Replace pool-weighted odds with a matching engine or automated market maker.	Tighter spreads, less slippage
05	Subnet evaluation Dedicated Avalanche subnet with a custom gas token, allowing the protocol to subsidise transaction cost entirely.	Removes the last friction point

THE ASK

Under \$10,000 to make settlement trustless.

Oracle integration ~40%

Optimistic resolution with bonded proposals and a dispute window. The core unlock for everything downstream.

Security review ~30%

Independent review of the market and factory contracts ahead of any mainnet deployment holding real value.

Infrastructure ~20%

Persistent event indexing, dedicated RPC capacity, and monitoring — replacing the on-demand scan with a durable listener.

Mainnet deployment ~10%

C-Chain deployment, initial market curation, and seed liquidity for launch markets.

Why this amount

The product is already built and deployed. We are not asking for runway to prove an idea — we are asking for the specific resources that close the gap between a working testnet application and something that can responsibly hold user funds.

What we deliver

Trustless resolution, a reviewed contract set, and a mainnet deployment on Avalanche C-Chain — with the same public verification standard we have held to on testnet.

TEAM & CONTACT

Small team, shipped product.

Hypa was designed, written, deployed, and verified by a team of three. Every contract, the indexer, and the interface were built in-house. The product in this deck is live and testable today — not a prototype, and not a mockup.
